APPENDIX · ALL 1,140 MULTI-MEMORY CALLS

How often is each displayed memory selected, by question?

Each cell conditions on that memory being present. “Selected” means the final implied $/hour uniquely matches that memory’s rate within ±3%. The fraction beneath the percentage is selected calls / calls where shown.

Darker = selected more often · Gold outline = pre-run domain/topic match · Denominator per question: A 32 · B 36 · C 52 · D 30 · E 48 · F 34 · G 36 · H 48 · I 48

Yes, most omitted memories are being crushed—but not all in the same way. C (Disney) and H (cleaner) dominate overall. B (Lyft) and D (toll) are weaker globally but activate in matching contexts. A (wage), E (parking search), G (declined shift), and I (gas) almost never control the final number; F (valet) is uncommon overall but activates strongly for rideshare.

Overall selection when shown

C Disney pass: 48%
H Apartment cleaner: 41%
D Toll road: 21%
B Lyft Wait & Save: 20%
F Valet on a date: 11%
A Wage: 8%
G Declined Saturday shift: 5%
I Cheaper gas station: 3%
E Free-parking search: 1%

Source: `runs/s2_combos/records.jsonl`. The design includes all 36 exact pairs plus three memory-addition ladders, so memories appear with different frequencies. Overall percentages therefore summarize this experimental mix, not a population frequency. Rows use all calls in which the named memory was present; exact pair-question cells alone have two repetitions.
